# Why do earthquakes happen?

Thermo chemical convection  
<http://geo.mff.cuni.cz/~cizkova/Anim/animace.htm>

From Namazu... to complex fluid dynamics

# Tectonic Forces & Convection

- The interior of the Earth is dynamic – it cools down and thus provides energy for convective currents in the outer core and in the asthenosphere.
- Additional energy comes from radioactive decay and Earth tides... enabling tectonic processes

# Plate Tectonics - Discovery

## Plate Tectonics - Mid-oceanic ridges

### Global ridge system

### Topography mid-atlantic ridge

The proof of plate tectonics came from the magnetization of the seafloor as a function of distance from the ridge axes.

# Tectonic plates

Tectonic plates are large parts of lithosphere 'floating' on the asthenosphere

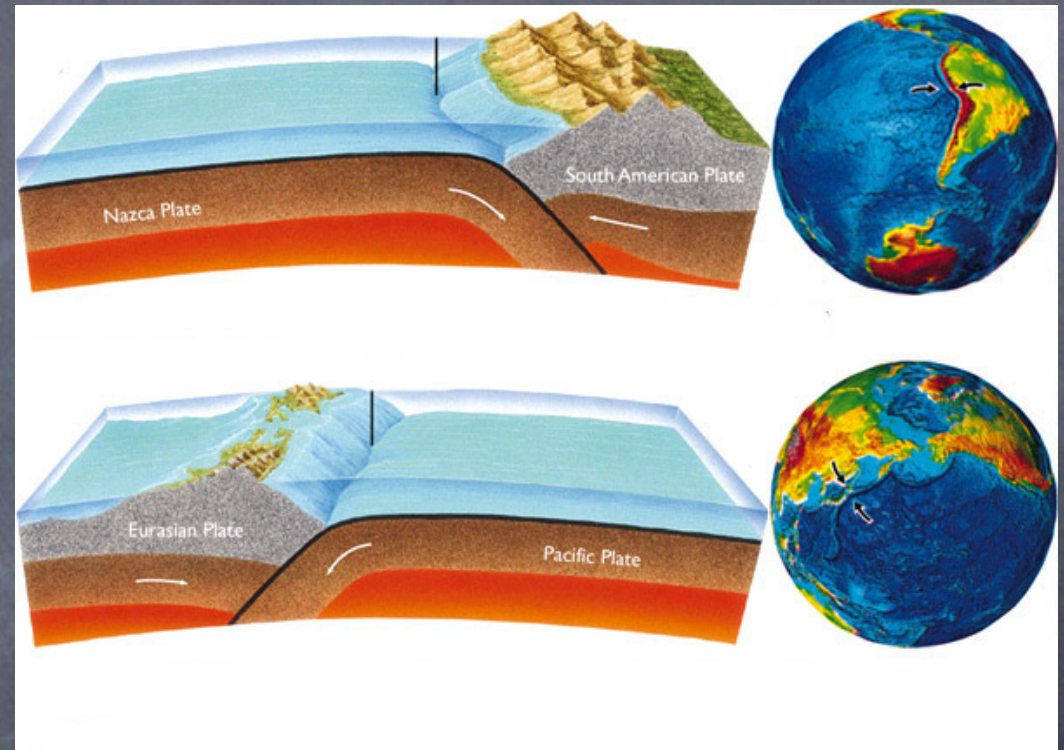

Convective currents, and other forces like Earth tides, move them around with velocities of several cm/year. The plates interact with one another in three basic ways:

- colliding (subduction zones)
- moving away from each other (spreading centers)
- sliding one past another

# Interacting plates

- Collision leads to **SUBDUCTION** of one plate under another. Mountain ranges may also be formed (Himalayas, Alps...).
- It produces strong and sometimes very deep earthquakes (up to 700 km).
- Volcanoes also occur there.

EXAMPLES: Nazca - South America  
- Eurasia - Pacific

# Interacting plates

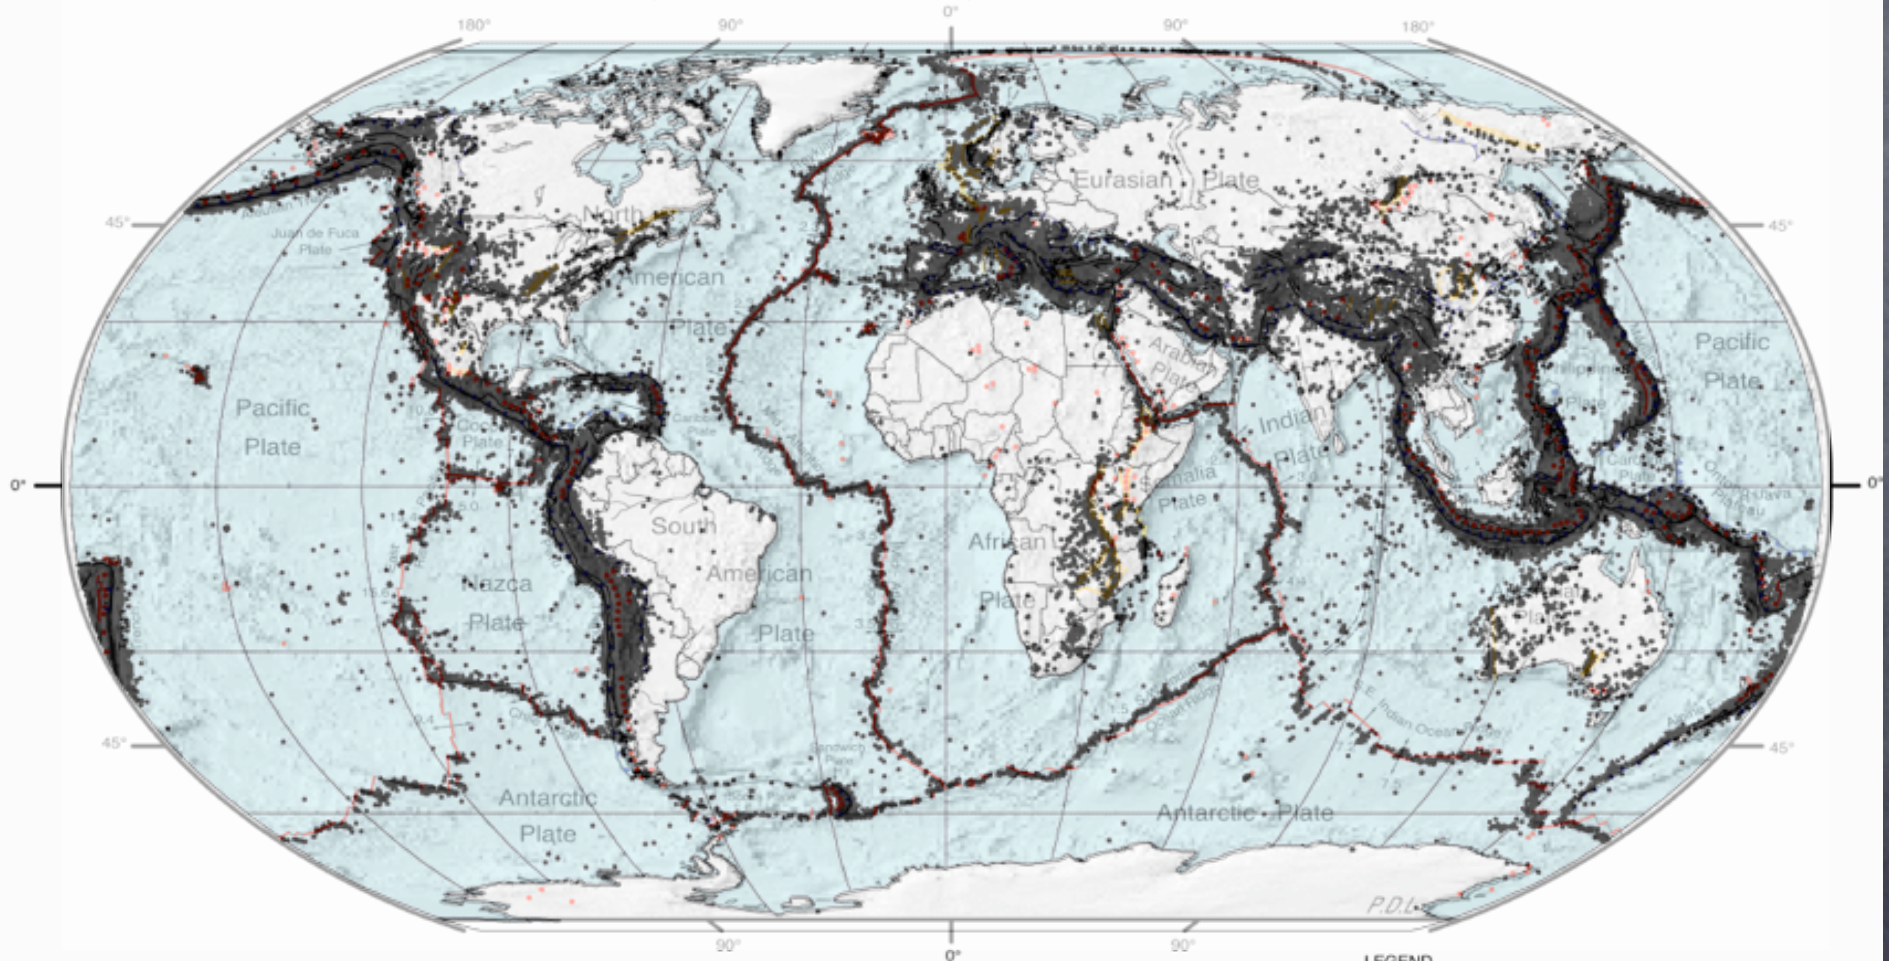

- Plates moving away from each other produce **RIDGES** between them (spreading centres).
- The earthquakes are generally weaker than in the case of subduction.

EXAMPLES: Mid-Atlantic ridge  
(African - South American plates,  
Euroasian -North American plates)

# Major tectonic plates

358,214 Events, 1963 - 1998

**DIGITAL TECTONIC ACTIVITY MAP OF THE EARTH**  
Tectonism and Volcanism of the Last One Million Years

**DTAM**

NASA/Goddard Space Flight Center  
Greenbelt, Maryland 20771

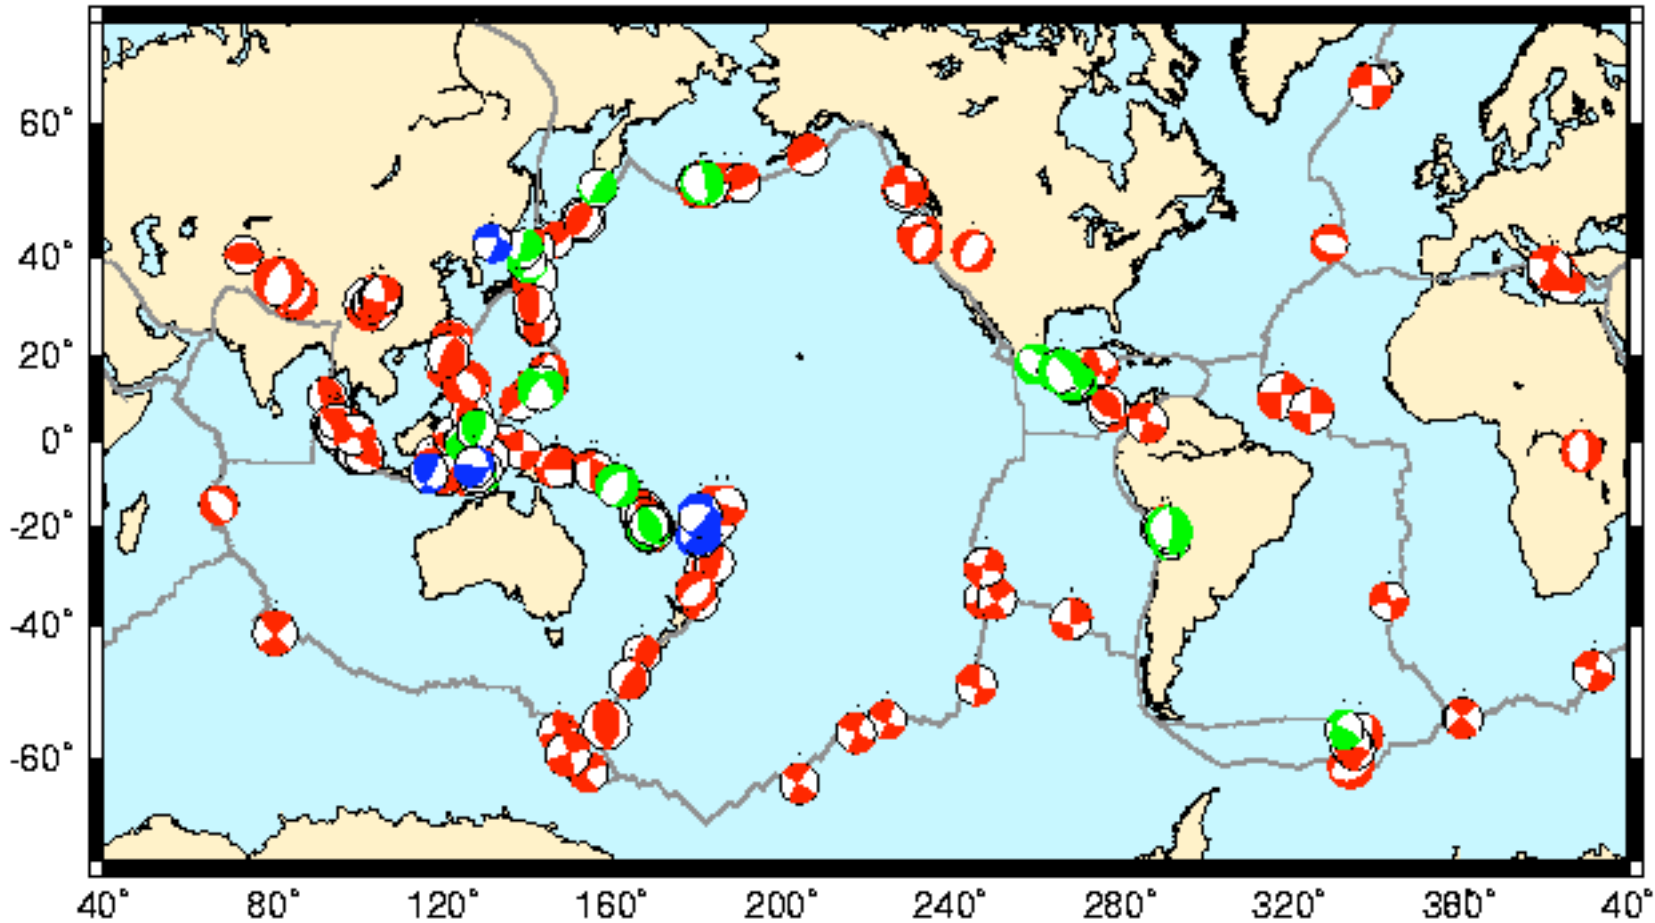

Robinson Projection  
October 1998

**LEGEND**

- Actively-spreading ridges and transform faults
- Total spreading rate, cm/year, NUVEL-1 model (DeMets et al., Geophys. J. International, 101, 425, 1990)
- Major active fault or fault zone; dashed where nature, location, or activity uncertain
- Normal fault or rift; hachures on downthrown side
- Reverse fault (overthrust, subduction zones); generalized; bars on upthrown side
- Volcanic centers active within the last one million years; generalized. Minor basaltic centers and seamounts omitted.

# Recent seismicity

GCMT Catalog - 01/01/2008-06/12/2008

[http://seismo.berkeley.edu/weekly/global\\_prev.html](http://seismo.berkeley.edu/weekly/global_prev.html)

# Plate tectonics

theory that is very young (1960-ies)

and provides answers to the most fundamental questions in seismology:

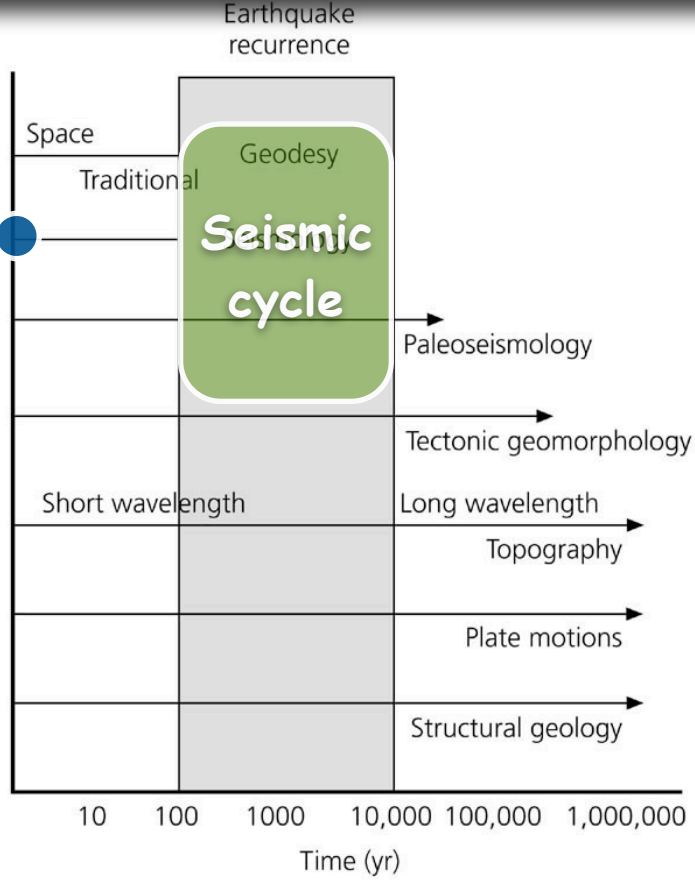

- 👁️ Why earthquakes occur?
- 👁️ Why are earthquake epicenters not uniformly distributed around the globe?
- 👁️ At what depths are their foci?

large, nearly rigid plates of the Earth slide past each other and

**earthquakes accommodate the motion**

Wave propagation

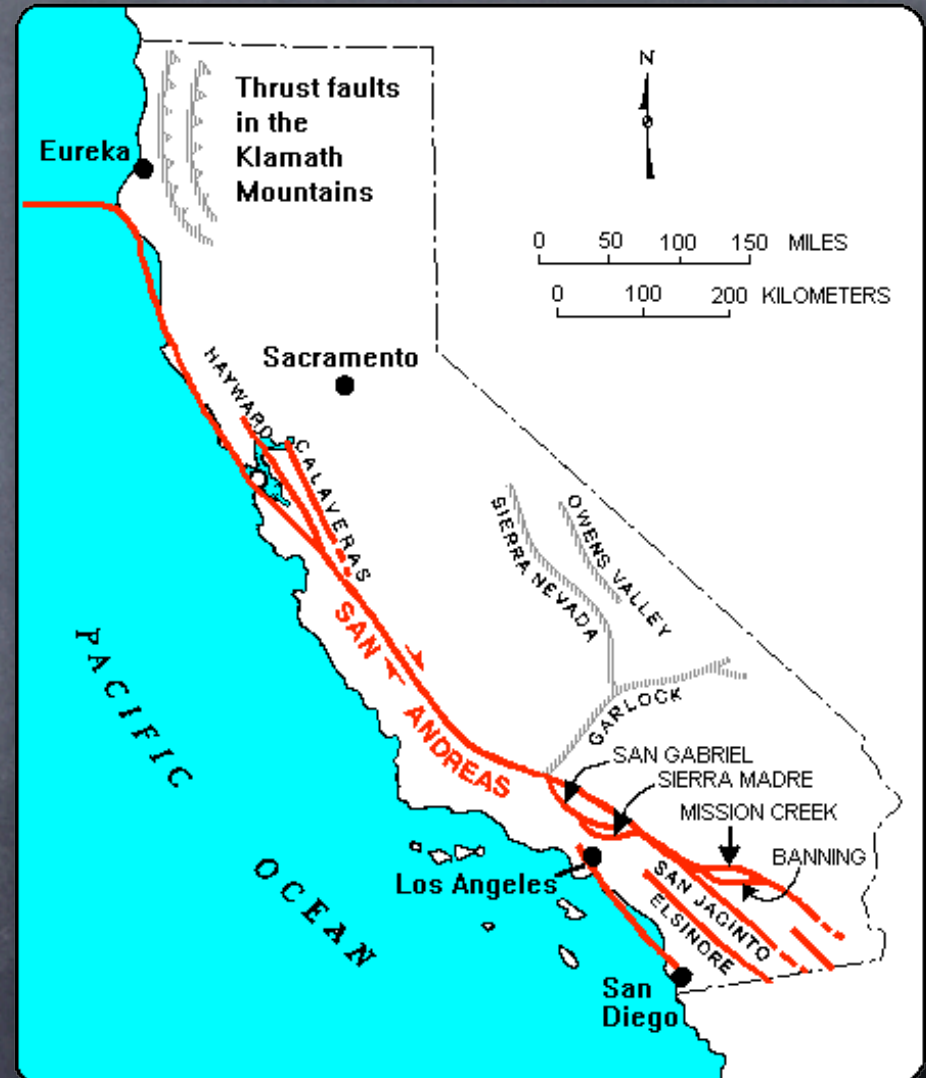

Different time scales...

# Plate Tectonics – Fault Zones

San Andreas Fault

Fault zones in California

# How earthquakes occur?

- 👁 Earthquakes occur at **FAULTS**.
- 👁 Fault is a weak zone separating two geological blocks.
- 👁 Tectonic forces cause the blocks to move relative one to another.

# What is an earthquake? Elastic rebound theory

- Because of friction, the blocks do not slide, but are deformed.
- When the stresses within rocks exceed friction, rupture occurs.
- Elastic energy, stored in the system, is released after rupture in waves that radiate outward from the fault.

# Earthquake (complex) cycle

# Rate ( $v$ ) and State ( $\theta$ ) Friction Constitutive Laws

$$\mu(\theta, V) = \mu_o + a \ln \left( \frac{V}{V_o} \right) + b \ln \left( \frac{V_o \theta}{D_c} \right)$$

state variable, characterizes physical state of surface or shearing region

critical slip distance

reference velocity

reference value of base friction

$$\frac{d\theta}{dt} = 1 - \frac{V\theta}{D_c}$$

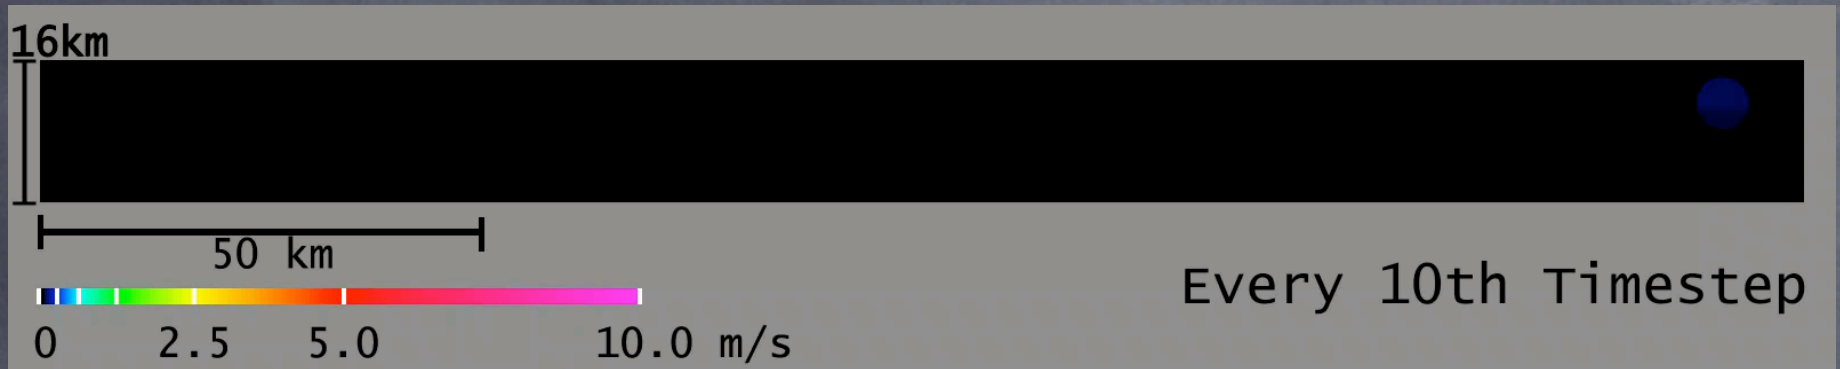

Dieterich, aging law

$$\frac{d\theta}{dt} = -\frac{V\theta}{D_c} \ln \left( \frac{V\theta}{D_c} \right)$$

Ruina, slip law

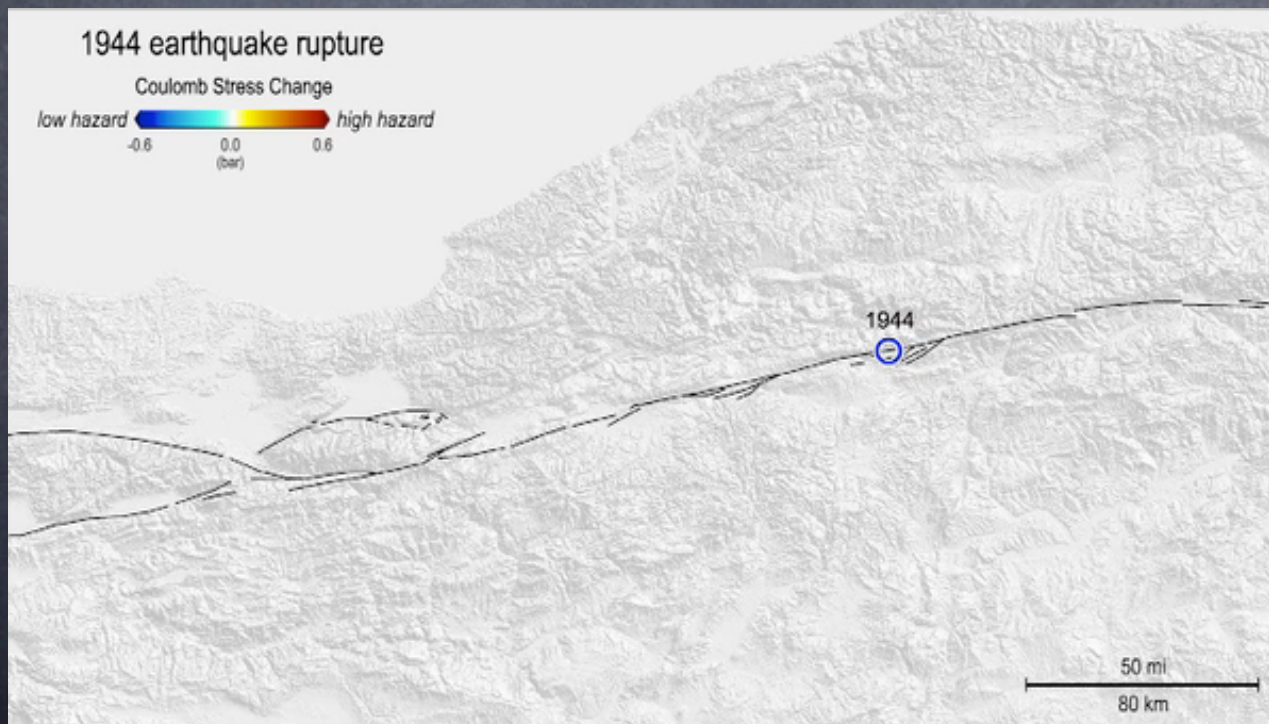

# Dynamic rupture and stress transfer

rupture velocities of a dynamic rupture model of a magnitude 7.7 on the southernmost San Andreas fault  
[www.scec.org](http://www.scec.org)

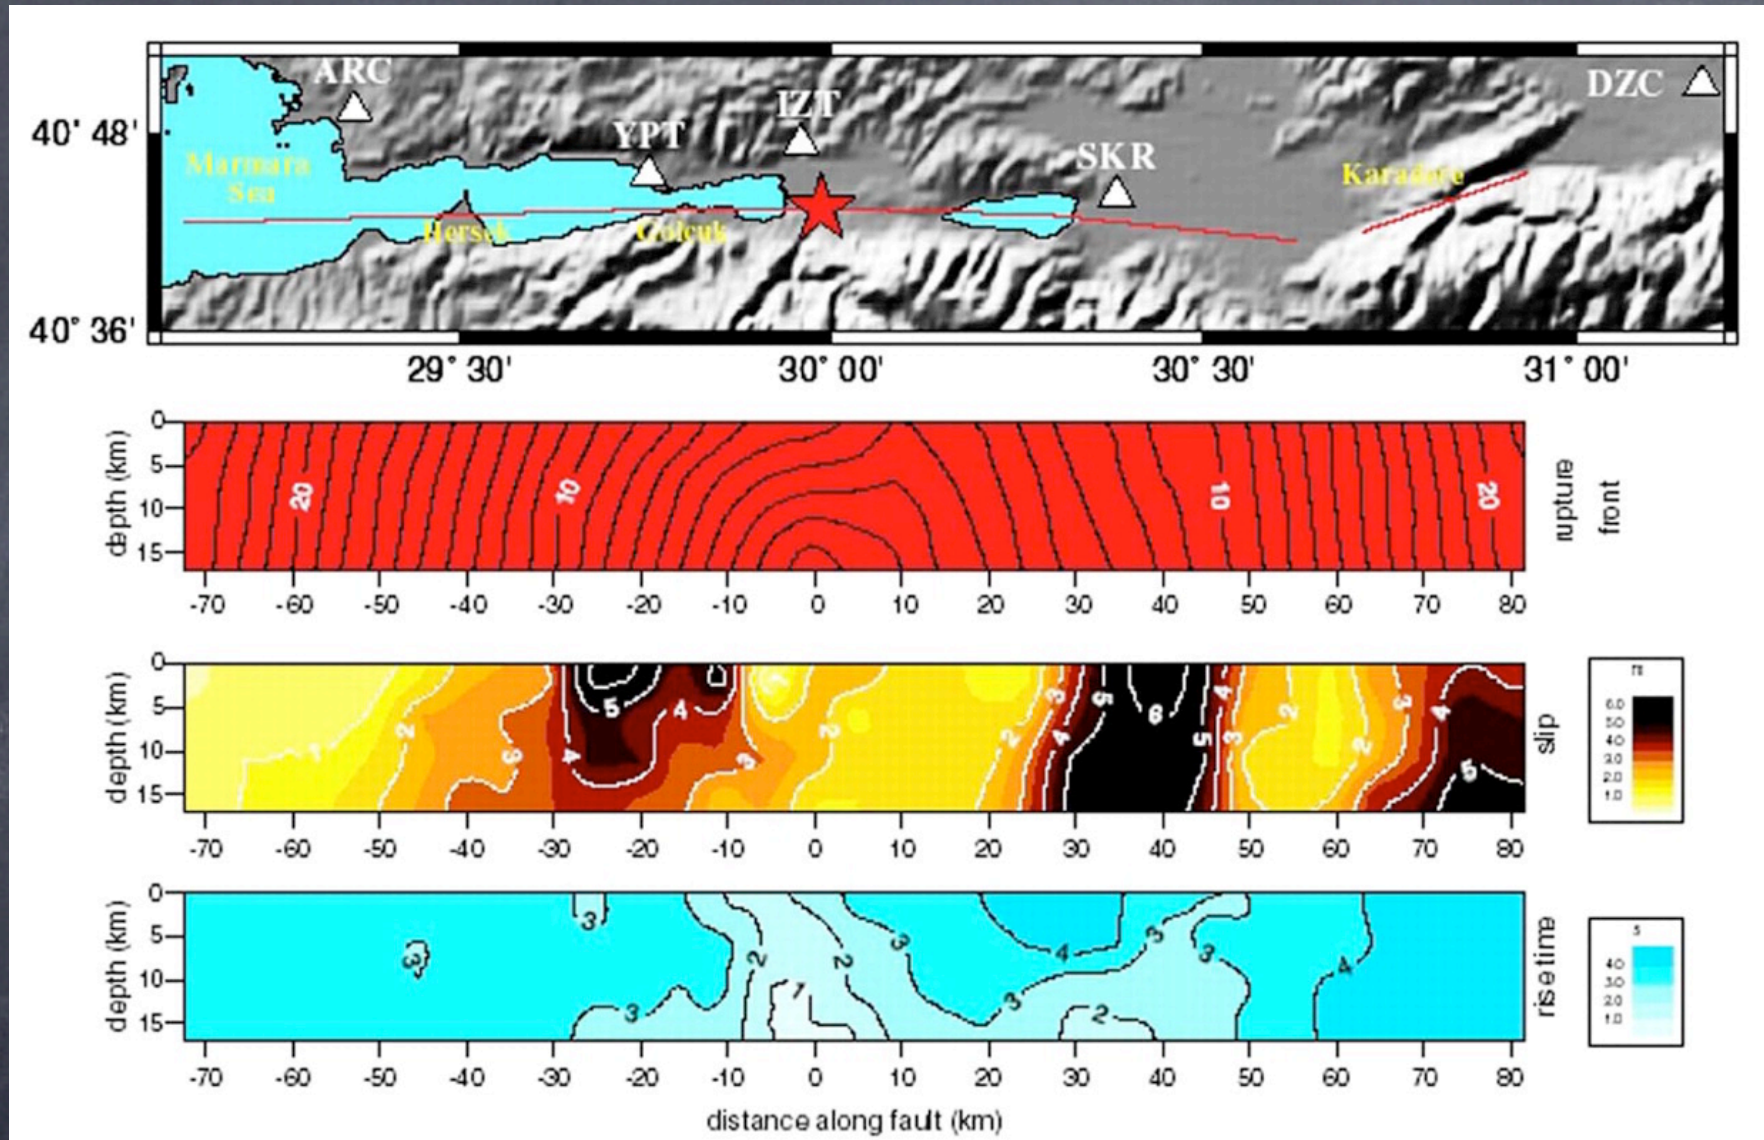

When a fault fails during an earthquake, it modifies the stress field in its surroundings. The modification of the stress pattern can give a rough idea of where the next shocks are more likely occur.

Coulomb stresses transmitted by seismic wave propagation for the M=7.2 1944 earthquake on the North Anatolian fault.

Courtesy of Kim B. Olsen

# Kinematic description

Map of the surface rupture of the **Izmit earthquake** (red line). The geometry of the fault model used in the inversion follows the red line but is continuous across the junction with the eastern segment. The symbols indicate the location of the epicenter (red star) and of the recording stations (triangles). Middle and bottom: Images of the rupture front, slip, and rise time on the fault.

The position of the rupture front is shown at 1-sec intervals from the beginning of the rupture. From: **Bouchon et al., 2002.**

**BSSA; v. 92; no. 1; p. 256-266**

# Ground motion scenarios

Surface Cumulative Peak Velocity Magnitude ( 3 sec)

■ PeakVelocity:0.0005 Lat:-117.4650 Long:34.2758

■ PeakVelocity:0.0004 Lat:-115.6840 Long:33.3579

Simulation2 (NW-SE)

100 km

Simulation3 (SE-NW)

The two views in this movie show the cumulative velocities for a San Andreas earthquake TeraShake simulation, rupturing south to north and north to south. The crosshairs pinpoint the peak velocity magnitude as the simulation progresses.

[www.scec.org](http://www.scec.org)

Any strategy for seismic risk reduction should be outlined trying to answer two basic questions:

① When, where and how big we have to expect a strong earthquake to strike a region?

② What should we expect when it occurs?

The answer to the first question is matter for earthquake prediction, while the second one is matter for sound seismic (&tsunami) hazard assessment...

# Earthquake effects

ground shaking

liquefaction

surface rupture

# Hazard, Risk & Vulnerability

$$\text{Risk} = \text{Hazard} * \text{Vulnerability}$$

Nature decided, and  
can be assessed

Man decided, and can  
be reduced

$$R = \langle H_i, P_i, C_i \rangle$$

set of i-events with  
possible adverse  
consequences

associated probabilities of  
their occurrence

associated  
intolerable  
consequences
